mapping_R Markup

Introduction to R packages for geospatial data

This tutorial introduces a variety of R packages that may be used to manipulate and visualize geospatial data in R. Below we provide short descriptions of the packages used in each example throughout this tutorial, which can to be installed with the following code:

Packages used in:

- EXAMPLE 1: Mapping Census Data
 - ACS & choroplethr can be used together to easily make choroplethGCT-PEPANNRES maps using data from the American Community Survey (ACS), yearly census data collected by the U.S. Census Bureau. To access ACS data you need an API key. Visit http://api.census.gov/data/key_signup.html, request a key, and paste it into the line below:
 - **choroplethrMaps** contains a global map and maps of the USA used by the choroplethr package.
- EXAMPLE 2: Working with Shapefiles, Projections, and Visualization
 - maptools contains functions for reading and manipulating geographic data, including ESRI shapefiles.
 - **rgdal** geospatial data abstraction and projection / transformation.
 - RColorBrewer provides color schemes that are especially useful for creating thematic maps.
 - **ggplot2** package for creating and customizing graphics is R.
 - rgeos contains functions for performing geometric analysis. For example gLength() calculates the length of input geometry, while gBuffer() adds a buffer to an input feature.
 - mapproj simple package for converting from latitude and logitude into projected coordinates.
- EXAMPLE 3: Migration Distances Map
 - maps another simple set of tools for creating maps, with links to several databases of spatial data.
 - geosphere supports trigonometric calculations for geographic applications. For example, computing distance to the horizon from a given location and altitude.
 - reshape reshapes data from 'wide' format (where repeated measurements are located across multiple columns) to 'long' format (where repeated measurements are spread across unique rows)
 - **mapproj** simple package for converting from latitude and logitude into projected coordinates.

Brief Overview:

EXAMPLE 1: Mapping Census Data

Packages used - ACS, choroplethr, choroplethrMaps

After installing packages (see introduction), load needed packages:

```
library(acs)
library(choroplethr)
library(choroplethrMaps)
```

We need an api key to access the ACS data. Visit http://api.census.gov/data/key_signup.html, request a key, and paste it into the line below:

```
api.key.install("<ACS API key>")
```

Great, now we have access to the census data. Table B19301 contains per capita income for the year of 2011. Lets plot it!

```
county_choropleth_acs(tableId="B19301")
```

Per capita income in the past 12 months (in 2011 inflation-adjusted dollars)

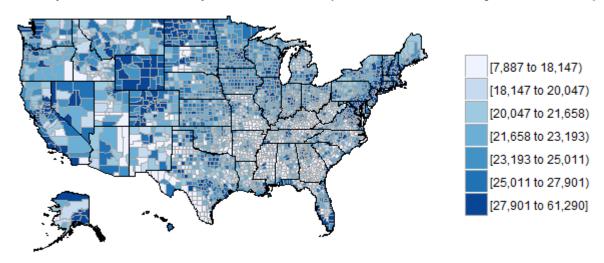

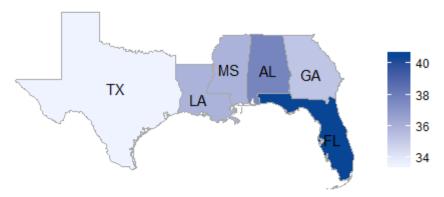

Figure 1: US county chloropleth using ACS per capita income data

To see the description of a function and its arguments in R, place a "?" before its name:

```
?county_choropleth_acs
```

You can explore the ACS data on the Census Bureau's website: http://factfinder.census.gov/faces/nav/jsf/pages/searchresults.xhtml Be sure to set the dataset to one of the ACS sources under Topics -> dataset. Use the ID column to find your tableID variable. Here's another example to get you started playing around with these functions:

Median Age by Sex: Median age -- Total:

EXAMPLE 2: Working with Shapefiles, Projections, and Visualization

Packages used - maptools, rgdal, RColorBrewer, ggplot2

After installing packages (see introduction), load needed packages:

```
library(maptools)
library(rgdal)
library(RColorBrewer)
library(ggplot2)
```

In this example we will work with the data provided along with this tutorial. Make sure you have unzipped the folder county_census before proceeding! The following prompts you to select the provided county census shapefiles at the path ... county census/County 2010Census DP1.shp.

```
counties <- readShapeSpatial(file.choose(),proj4string=CRS("+proj=longlat +datum=WGS84"))</pre>
```

Note that the second parameter of the maptools function readShapeSpatial was a string representing the projection of the data, called a prj4 string. So far we've used "+proj=longlat +datum=WGS84", which is simply unprojected longitude and latitude coordinates.

Inspect the first few rows of the counties data to get a feel for its structure:

head(counties@data)

Census data assigns codes to counties using the Federal Information Processing Standard (FIPS). A FIPS code starts with two digits representing the state, and is followed by three digits representing the county. For

example, Florida is 12 and Clay County Florida is 12019. To select all the counties in Florida we can use a regular expression matching all codes that start with "12":

```
florida <- counties[substring(counties$GEOID10,1,2)=="12",]
plot(florida)</pre>
```

You can look up other state and county codes using the U.S. Census Bureau site: https://www.census.gov/geo/reference/codes/cou.html

Projection and Layering with RGDAL

Next we'll work more with projections using library rgdal. We're going to read in a shape file of cultural points in Florida from the supplied data, again using function readShapeSpatial(). We know already that our cultural centers layer uses NAD83(HARN) / Florida GDL Albers. We can make the EPSG data frame of projections to find the prj4 string for this projection (use ?make_EPSG() to find out more about this table):

```
library(rgdal)
EPSG <- make_EPSG()</pre>
```

We can use regular expressions to search the note field of EPSG for any that refer to Florida:

```
EPSG[grep("florida", EPSG$note, ignore.case=TRUE), 1:2]
```

```

                          # NAD83(2011) / Florida West
## 3079
        6442
## 3080
                   # NAD83(2011) / Florida West (ftUS)
        6443
## 3747 26758
                                # NAD27 / Florida East
                                # NAD27 / Florida West
## 3748 26759
## 3749 26760
                               # NAD27 / Florida North
## 3895 26958
                                # NAD83 / Florida East
## 3896 26959
                                # NAD83 / Florida West
                               # NAD83 / Florida North
## 3897 26960
```

We see the code we're looking for is 3087. Extract the prj4 string from this dataframe:

```
subset(EPSG, code==3087)
prjstring <- subset(EPSG, code==3087)$prj4</pre>
```

Inspect our pristring variable if you want to see the format of the pri4 variable.

Now that we have the appropriate prj4 we can read in the cultural centers data. The following prompts you to select the shape file. Select the actual .shp file in the provided data from ...cultural_centers/gc_culturecenter_oct15.shp.

```
cultural <- readShapeSpatial(file.choose(),proj4string=CRS(prjstring))</pre>
```

Before we overlay the cultural points, we need to transform this layer to match that of the Florida counties layer - simple longitude and latitude in WGS84:

```
cultural_proj <- spTransform(cultural, CRS("+proj=longlat +datum=WGS84"))
plot(florida)
points(cultural_proj)</pre>
```

You can play around with the symbology for your map with some additional arguments in the points function. For example:

```
plot(florida)
points(cultural_proj, cex=.8, pch=24, col=554, bg="grey")
```

join polygon data to points

```
county_data <- over(cultural_proj,florida)
cultural_proj$pop <- county_data$DP0010001</pre>
```

set colors

```
library(RColorBrewer)
```

```
brks <- c(.5,1,1.5,2) * 1000000
cols <- brewer.pal(5,"Greens")</pre>
```

```
mapcols <- cols[findInterval(cultural_proj$pop, vec=brks)]
plot(cultural_proj,col=mapcols,pch=20)</pre>
```

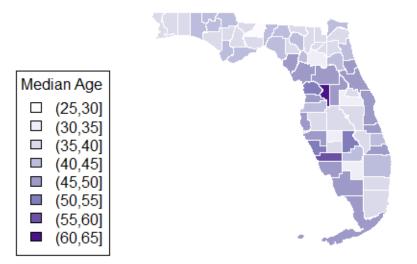

base R instructions for choropleth

```
brks <- c(25,30,35,40,45,50,55,60,65)
cols <- brewer.pal(8,"Purples")

mapcols <- cols[findInterval(florida$DP0020001, vec=brks)]
plot(florida,col=mapcols,border="white")

legend("bottomleft", legend = levels(cut(florida$DP0020001, brks)), fill = cols, title = "Median Age")</pre>
```

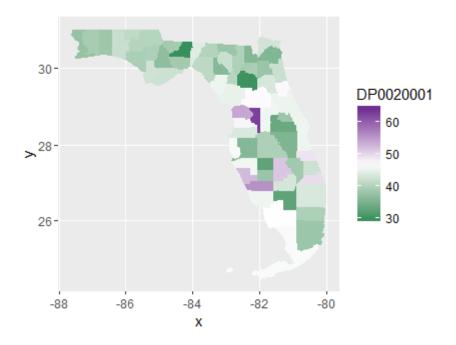

using ggplot2

library(ggplot2)

```
fl_shapes <- fortify(florida,region="GEOID10")</pre>
```

```
ggplot() + geom_map(data=as.data.frame(florida),aes(map_id = GEOID10,fill=DP0020001), map=fl_shapes) +
```

EXAMPLE 3: Migration Distances Map

Packages used - maps, geosphere, reshape, maptools

After installing packages (see introduction), load needed packages:

```
library(maps)
library(geosphere)
library(reshape)
library(maptools)
```

Import shapefile and .csv file

Import shapefile of map of continental United States. Choose state_shapes/tl_2014_us_state.shp file when prompted.

```
state <- readShapeSpatial(file.choose())</pre>
```

Import data file of migration distances between U.S.A. states. Choose state_migrations_2014.csv file when prompted.

```
migration <- read.csv(file.choose())</pre>
```

Extract state names and geographic coordinate (latitude and longitude) information from state shapefile; save it into a data frame called centrs.

```
centrs <- data.frame(as.character(state@data$NAME),coordinates(state))
colnames(centrs) <- c("name","long","lat")</pre>
```

Reshape data with melt function

Redefine the migration data set to only include columns 1 & 6-through-56 of data. Then use melt function from reshape package to transform data set into rows representing unique instances of data, based on a selected variable id (in our case, the from_state variable). For more on the melt function, see https://www.r-bloggers.com/melt/.

```
migration <- migration[c(1,6:56)]
long_mig <- melt(migration,id.vars="from_state")</pre>
```

Create a mapping function

Create a function named data_from_state that maps migration distances from any state selected. NOTE: To use this function, a map must be drawn (i.e. a new plot must be called) first.

```
draw_from_state <- function(centrs, migrations, state_name, color=rgb(0,0,0,alpha=0.5)) {
    migrations$variable <- sub("."," ",migrations$variable,fixed=TRUE)
    migrations <- migrations[migrations$variable==state_name & migrations$from_state != state_name,]
    for(i in 1:nrow(migrations)){
        if (nrow(centrs[centrs$name==as.character(migrations[i,]$from_state),]) > 0){
            from_long <- centrs[centrs$name==as.character(migrations[i,]$from_state),]$long
            from_lat <- centrs[centrs$name==as.character(migrations[i,]$from_state),]$lat
            to_long <- centrs[centrs$name==as.character(migrations[i,]$variable),]$long
            to_lat <- centrs[centrs$name==as.character(migrations[i,]$variable),]$lat
            number <- migrations[i,]$value
            lines(gcIntermediate(c(from_long, from_lat), c(to_long, to_lat), n=50, addStartEnd=TRUE),lw
        }
    }
}</pre>
```

Using our mapping function: example 1

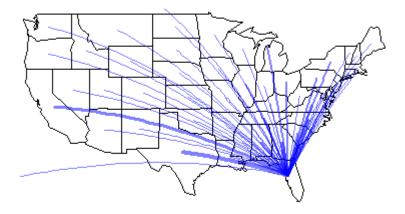

First draw imported state shapefile.

map("state")

Now use written function to map migration distances from Florida.

draw_from_state(centrs, long_mig, "Florida", rgb(0,0,1,0.5))

Using our mapping function: example 2

First draw a world map (limited to North and Central America by creating x- and y-coordinate limits), and subsquently use written function to map migration distances from Wyoming onto map.

```
xlim <- c(-171.738281, -56.601563)
ylim <- c(12.039321, 71.856229)
map("world", col="#f2f2f2", fill=TRUE, bg="white", lwd=0.05, xlim=xlim, ylim=ylim)
draw_from_state(centrs, long_mig, "Wyoming", rgb(1,0,0,.5))</pre>
```
